BLUEPRINT OF AN ARCHITECTURAL MASTERPIECE

The erection of the pillars - auto-stable - above the first floor was less difficult.

As for the tower, it was erected with even less difficult, apart from working at heights ...

The principle behind the structure reveals two apparent sections where it is in tension :

- the horizontal connections on the first floor (7-meter wide girders)
- the base of the tower top

These two points will be brought up farther on.

The structure was made of puddle iron and not steel. The Tower was assembled using a limited number of fabricated parts, evident in the list taken from Mr. Eiffel's book:

Several other cast iron parts could be joined to this list of which 16 truss supports, connecting the masonry and the structure.

To obtain the 300 meters, the Tower is basically composed of two elements :

- a base, which is a sort of bar stool, very sturdy, standing on 4 main pillars that are bonded and extended with a much lighter batter at the smaller level that constitutes the second floor,
- a tower firmly attached atop.

The value of the pillar base is directly related to the swaying caused by wind forces.

The greatest difficulty in erecting it was the bonding of the four main pillars at the first floor.

Considering the available equipment of the period, it was necessary to implant as precisely as possible four bases 80 meters apart from each other and then to raise the four pillars at a slant and to prop them up employing millimeter precision fifty meters above the ground.
